

Chapter 1: Linear Equations in linear algebra - vector equations

Summary

Vectors exist in \mathbb{R}^n space. You can add vectors in the same \mathbb{R}^n . A vector or a collection of vectors will have a span. The span is all the points in \mathbb{R}^n space the vector(s) can reach. You can tell if a vector exists in a span by making an augmented matrix and testing if the system is consistent.

Terminology

Vector

- list of ordered numbers
- matrix with **single** column
- arrow on top, could be bar on bottom

Scalar multiple

- multiplying each entry of v by c
- scale a vector

\mathbb{R}^n

- n-dimensional real space
- the set of all column vectors with n real entries
- $\mathbb{R}^n = \{(x_1 \ x_2 \ \dots \ x_n) \mid x_1, x_2 \ \dots \ x_n \in \mathbb{R}\}$

Zero vector

- all entries zero
- a zero vector of each size ($\mathbb{R}^1, \mathbb{R}^2 \ \dots \ \mathbb{R}^n$)
- but it should be clear from context what size is meant
- Graphically it's just the origin

parallelogram rule

- adding vectors tip and tail

weights

- constants in front of vectors

linear combinations

- adding $v_1, v_2 \ \dots \ v_n$ with weights $c_1, c_2 \ \dots \ c_n$

span

- the set of all linear combinations of v_1, \dots, v_n

Vectors

Two vectors in \mathbb{R}^n are equal if their corresponding entries are equal

$(1 \ -2) \neq (-2 \ 1)$
order matters!

\mathbb{R}^n

\mathbb{R}^1 = real line

$\{x | x \in \mathbb{R}\}$

\mathbb{R}^2 = real plane

$\{(x \ y) | x, y \in \mathbb{R}\}$

Like cartesian plane but instead of (x, y) we use vector notation. $(x \ y)$ *vertical*

Arithmetic of vectors in \mathbb{R}^n

The sum of two vectors are obtained by adding the corresponding entries. (Slap em' together)

1. $u+v = v+u$
2. $(u+v)+w = u+(v+w)$
3. $(u+0) = u$
4. $u+(-u) = 0$
5. $c(u+v) = cu+cv$
6. $(c+d)u = cu+du$
7. $c(du) = (cd)u$
8. $1u = u$

Spans

The span of a single vector (multiply it by any Real number). The set of all multiples of that vector. Will get a line as long as it isn't a zero vector

in \mathbb{R}^2 , if we take another vector w not on the line, and not a zero vector, then $\text{span}\{v, w\}$ is any Real number in \mathbb{R}^2 .

in \mathbb{R}^3 , if we take another vector w not on the line, and not a zero vector, then $\text{span}\{v, w\}$ is a plane through the origin in \mathbb{R}^3 space containing w and v .

$$\text{span}\{0\} = 0$$

$$\text{span}\{v, 2v\} = \text{span}\{v\} \text{ // line through } v \text{ and } 0$$

Representing a linear system using vector equations

$$x_1 - 2x_2 + x_3 = 5$$

$$x_1 - x_2 - x_3 = 0$$

==

$$x_1 \begin{pmatrix} 1 \\ 1 \end{pmatrix} + x_2 \begin{pmatrix} -2 \\ -1 \end{pmatrix} + x_3 \begin{pmatrix} 1 \\ -1 \end{pmatrix} = \begin{pmatrix} 5 \\ 0 \end{pmatrix}$$

solving a linear system is equivalent to finding a linear combination of the coefficient vectors which is equal to a particular other vector

From the point of view of spans, asking if b is in $\text{span}\{v_1, \dots, v_p\}$ is the same as asking if $x_1v_1 + x_2v_2 + \dots + x_pv_p = b$ has a solution. That is the same as asking if the system with augmented matrix is consistent.

Row Reduction Answers this!
